1/4

the sp imn was applied as a standard technique in most rcts included in our meta-analysis, the insertion of the sp nail is a technically simple procedure compared with the ip insertion. fixation of the distal end of the imn is easier in the sp approach. this approach does not necessitate the need for fluoroscopy, bone graft, or bone screw placement. in addition, the sp approach is only suitable for distal tibia fractures. in contrast, the ip imn is applicable to fractures of any level. however, the ip approach increases the risk of soft tissue damage and bleeding. further study is required to compare the effectiveness of the two techniques for distal tibia fractures, intraoperative fluoroscopy radiation exposure can significantly increase the risk of malignancy. however, it is suggested that intraoperative fluoroscopy is used for the sp approach, and the use of the sp approach during closed reduction is strongly recommended for fractures with severe comminution. in our study, an average of 1.48 (sd 1.0) fluoroscopy times per patient was used for the sp group, whereas 1.11 (sd 0.8) times were used for the ip group. these results indicate that the sp approach is beneficial for patients in terms of intraoperative fluoroscopy radiation exposure, the sp approach was used for treating patients with distal tibial fractures with severe comminution, and the fracture was reduced in the extended position, thereby reducing the amount of intraoperative fluoroscopy radiation exposure to the surgeon, in this study, the quality of all included rcts was evaluated using the cochrane risk of bias tool. most of the included trials were judged as having an unclear or high risk of bias in several domains, including random sequence generation, allocation concealment, and blinding of participants and

personnel. all of the trials included in the meta-analysis had unclear or high risk of bias in terms of blinding of participants and personnel, which may have affected the findings of the present study. one trial [11] used an open-label design. all of the included rcts demonstrated a jadad scale score of three or higher, and there was no evidence of publication bias in the funnel plot. the overall methodological quality of the included studies was high. however, all of the studies except one were performed with low sample sizes, and all of the included studies had a follow-up period of less than 18months. because of the potential for performance and detection bias, our findings should be interpreted with caution. further high-quality, randomized, controlled trials with larger sample sizes and longer follow-up periods are needed to further confirm these results.
